DEVICES AND METHODS FOR SELECTIVELY FILTERING MESSAGE CONTENT

This application is a continuation of U.S. patent application Ser. No. 12/580,700, filed Oct. 16, 2009, now U.S. Pat. No. 8,301,168.

TECHNICAL FIELD

The present disclosure relates generally to content filtering and, more particularly, to devices and methods for selectively filtering message content based upon location and/or user presence status.

BACKGROUND

Text and multimedia messaging are popular methods of communication used by an increasing number of wireless service subscribers worldwide. Text messaging offers a convenient way for people to engage in quick, text-based conversations. Multimedia messaging offers a similarly convenient way for people to exchange images, audio, and/or video, sometimes in addition to text.

Most text and multimedia messaging sessions can be conducted in a discrete manner. When a user is not available to receive an incoming message, the message may be inadvertently disclosed to prying eyes or may be subject to discovery by co-workers, family, friends, or other people who the user does not want viewing the message for one reason or another.

SUMMARY

According to one aspect of the present disclosure, a method for selectively filtering message content received at a mobile device based upon a current location of the mobile device is disclosed. The method includes detecting a message being received at a mobile device. The message includes message content that is considered appropriate or inappropriate based upon a current location of the mobile device and a filtering rule established for the current location. The method further includes determining the current location of the mobile device using a location component of the mobile device and analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location. If it is determined that the message content is appropriate, the method further includes presenting all of the message content to a user of the mobile device. If it is determined that any portion of the message content is inappropriate, the method further includes modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the mobile device is at the current location, presenting only the appropriate portion of the message content to the user of the mobile device, monitoring movement of the mobile device from the current location to a safe location, whereat a filtering rule established for the safe location considers the inappropriate portion of the message content to be appropriate when the mobile device is at the safe location, modifying the message content based upon the filtering rule established for the safe location, such that previously considered inappropriate portion is available to the user when the mobile device is at the safe location; and presenting the message content to the user of the mobile device.

In some embodiments, the message is a text message and the message content is text. In other embodiments, the mes-

2

sage is a multimedia message and the message content is some combination of text, graphics, audio, and video.

In some embodiments, the filtering rule is established for the current location and an additional location. In other embodiments, the filtering rule is defined based upon criteria set by the user of the mobile device. In still other embodiments, the filtering rule is defined based upon criteria set by the user of the mobile device. In further embodiments, the filtering rule is defined based upon criteria set by a wireless service provider. In some embodiments, the filtering rule is defined based upon a content rating assigned to the message content.

In some embodiments, modifying the inappropriate portion of the message content includes blocking the inappropriate portion of the message content, and modifying the message content based upon the filtering rule established for the safe location includes unblocking the previously considered inappropriate portion of the message content. In other embodiments, modifying the inappropriate portion of the message content includes temporarily removing the inappropriate portion of the message content, and modifying the message content based upon the filtering rule established for the safe location includes adding the previously considered inappropriate portion of the message content back into the message content. In still other embodiments, modifying the inappropriate portion of the message content includes altering the inappropriate portion of the message content, and modifying the message content based upon the filtering rule established for the safe location includes undoing the altering of the previously considered inappropriate portion of the message content.

According to another aspect of the present disclosure, a mobile device is configured to selectively filter message content based upon a location of the mobile device. The mobile device includes a transceiver for receiving message content, a processor, and a memory, in communication with the processor, the memory being configured to store instructions that are executable by the processor to carry out various functions. The instructions cause the processor to detect a message being received, via the transceiver, at the mobile device. The message includes message content that is considered appropriate or inappropriate based upon a current location of the mobile device and a filtering rule established for the current location. The instructions further cause the processor to determine the current location of the mobile device using a location component of the mobile device, and analyze the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location. If it is determined that all of the message content is appropriate, the instructions cause the processor to present the message content to a user of the mobile device. If it is determined that any portion of the message content is inappropriate, the instructions cause the processor to: modify the inappropriate portion of the message content, such that the inappropriate portion is not available to the user when the mobile device is at the current location, present only the appropriate portion of the message content to the user of the mobile device, monitor movement of the mobile device from the current location to a safe location, whereat a filtering rule established for the safe location considers the inappropriate portion of the message content to be appropriate when the mobile device is at the safe location, modify the message content based upon the filtering rule established for the safe location, such that previously considered inappropriate portion is available to the user when the mobile device is at the safe location, and present the message content to the user of the mobile device.

3

According to another aspect of the present disclosure, a method for selectively filtering message content received at a mobile device based upon a current presence status of a user of the mobile device includes detecting a message being received at a mobile device. The message includes message content that is considered appropriate or inappropriate based upon a current presence status of the mobile device and a filtering rule established for the current presence status. The method further includes analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current presence status.

If it is determined that the message content is appropriate, the method further includes presenting the message content to a user of the mobile device. If it is determined that any portion of the message content is inappropriate, the method further includes modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the current presence status is active, presenting only the appropriate portion of the message content to the user of the mobile device, detecting a change from the current presence status to a new presence status, the new presence status triggering a new filtering rule to be implemented that considers the previously considered inappropriate portion of the message content as being appropriate for the new presence status, modifying the message content based upon the new filtering rule, such that the previously considered inappropriate portion is available to the user, and presenting the message content to the user of the mobile device.

In some embodiments, the filtering rule is defined based upon criteria set by the user of the mobile device. In some embodiments, the filtering rule is defined based upon a content rating assigned to the message content. In some embodiments, the filtering rule is defined based upon criteria set by a wireless service provider.

In some embodiments, modifying the inappropriate portion of the message content includes blocking the inappropriate portion of the message content and modifying the message content based upon the new filtering rule includes unblocking the previously considered inappropriate portion of the message content. In other embodiments, modifying the inappropriate portion of the message content includes temporarily removing the inappropriate portion of the message content and modifying the message content based upon the filtering rule established for the safe location includes adding the previously considered inappropriate portion of the message content back into the message content. In other embodiments, modifying the inappropriate portion of the message content includes altering the inappropriate portion of the message content and modifying the message content based upon the new filtering rule includes undoing the altering of the previously considered inappropriate portion of the message content.

In some embodiments, the message is a text message including text as the message content. In other embodiments, the message is a multimedia message including some combination of text, graphics, audio, and video.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates an exemplary wireless communications network system in which the devices of the present disclosure may operate, according to an embodiment of the present disclosure.

FIG. 2 illustrates an exemplary mobile device and components thereof, according to an embodiment of the present disclosure.

4

FIG. 3 illustrates an exemplary method for selectively filtering message content received at a mobile device based upon a current location of the mobile device, according to an embodiment of the present disclosure.

FIG. 4 illustrates an exemplary method for selectively filtering message content received at a mobile device based upon a current presence status of the mobile device, according to an embodiment of the present disclosure.

FIG. 5 illustrates an exemplary Graphical User Interface (GUI) of a message content filtering application operating on the exemplary mobile device of FIG. 2, according to one embodiment of the present disclosure.

FIG. 6 illustrates a GUI of a message content filtering application operating on the exemplary mobile device of FIG. 2, according to another embodiment of the present disclosure.

DETAILED DESCRIPTION

As required, detailed embodiments of the present disclosure are provided herein. The disclosed embodiments are merely examples that may be embodied in various and alternative forms, and combinations thereof. As used herein, for example, exemplary, and similar terms, refer expansively to embodiments that serve as an illustration, specimen, model or pattern. The figures are not necessarily to scale and some features may be exaggerated or minimized, such as to show details of particular components. In some instances, well-known components, systems, materials or methods have not been described in detail in order to avoid obscuring the devices and methods of the present disclosure. Therefore, specific structural and functional details disclosed herein are not to be interpreted as limiting, but merely as a basis for the claims and as a representative basis for teaching one skilled in the art to variously employ the present disclosure.

The devices and methods of the present disclosure are described in context of a Global System for Mobile communications (GSM) network and a Universal Mobile Telecommunications System (UMTS) network and, in particular, wireless messaging within these network types. It should be understood that the present disclosure is not limited to GSM and UMTS networks. Rather, the present disclosure is applicable to any existing or yet to be developed telecommunications technology that supports Short Message Service (SMS) messaging, Enhanced Message Service (EMS) Messaging, and/or Multimedia Message Service (MMS) messaging services. Some examples of other suitable telecommunications technologies include, but are not limited to, networks utilizing Time Division Multiple Access (TDMA), Frequency Division Multiple Access (FDMA), Wideband Code Division Multiple Access (WCDMA), Orthogonal Frequency Division Multiplexing (OFDM), and various other 2G, 2.5G, 3G (third generation), and above (4G and beyond) technologies. Examples of suitable data bearers, for example to support multimedia messaging services, include General Packet Radio Service (GPRS), Enhanced Data rates for Global Evolution (EDGE), the High-Speed Packet Access (HSPA) protocol family, such as, High-Speed Downlink Packet Access (HSPDA), Enhanced Uplink (EUL) or otherwise termed High-Speed Uplink Packet Access (HSUPA), Evolved HSPA (HSPA+), and various other current and future data bearers.

While the methods of the present disclosure are often described in a general context of computer-executable instructions, the methods of the present disclosure can also be implemented in combination with other program modules and/or as a combination of hardware and software. The term application, or variants thereof, is used expansively herein to include routines, program modules, programs, components,

data structures, algorithms, and the like. Applications can be implemented on various system configurations, including single-processor or multiprocessor systems, minicomputers, mainframe computers, personal computers, hand-held computing devices, microprocessor-based, programmable consumer electronics, combinations thereof, and the like.

Referring now to FIG. 1, an exemplary wireless communications network **100** is illustrated, according to an embodiment of the present disclosure. The wireless communications network **100** provides a suitable environment in which mobile devices exchange messages including, for example, Short Message Service (SMS), Enhanced Message Service (EMS), and Multimedia Message Service (MMS) messages. The messages each include message content, which includes text, graphics, audio, and/or video.

Text may include numbers, letters, characters, symbols, combinations thereof, and the like. Graphics may include images, pictures, computer-generated graphics, combinations thereof, and the like. Audio may include music, ringtones, spoken word, podcasts, sounds, combinations thereof, and the like. Video may include recorded video, live video, animated video, video, computer-generated video, combinations thereof, and the like.

The illustrated wireless communications network system **100** includes two wireless networks, wireless network A **102** and wireless network B **104**. The illustrated wireless network A **102** includes a mobile device **106**, such as a cellular telephone, wireless messaging device, computer of any form factor (e.g., laptop, notebook, netbook, subnotebook, etc.), or the like. As a computer, the mobile device **106** may be configured with a fixed or removable network access card (not shown) to allow a user to access the wireless network A **102**. In this embodiment, the computer may also be configured with messaging software to support SMS, EMS, and/or MMS messaging.

The illustrated mobile device **106** is in communication with a radio access network (RAN) **108**. The RAN **108** includes at least one base transceiver station (BTS), commonly referred to as a cell tower. The BTS provides the air/radio interface by which the mobile device communicates wirelessly with wireless network A **102**. Each BTS is in communication with a base station controller (BSC) (not shown). A BSC allocates radio resources to the mobile device, administers frequencies, and controls handovers between BTSs. A BSC communicates with a circuit-switched core network and packet-switched core network via a mobile switching center (MSC) and serving GPRS support node (SGSN), respectively (components not shown). MSC, SGSN and other network elements of the core networks are not illustrated so as not to distract from the various aspects of the present disclosure.

Wireless network A **102** also includes an SMS service center (SMSC) **110** and an MMS service center (MMSC) **112**, both illustrated as being capable of communication with wireless network B **104** through an SMSC **114** and an MMSC **116** of wireless network B **104**. The SMSCs **110**, **114** are a combination of hardware and software, and are responsible for receiving, storing, and forwarding SMS messages in accordance with SMS standard protocols. In some embodiments, SMS messages are received from a sending mobile device (e.g., the mobile device **106** or the mobile device **120**), stored until a recipient mobile device (e.g., the mobile device **120** or the mobile device **106**) is available, and forwarded to the recipient mobile device. In other embodiments, SMS messages are received from an SMS entity (not shown), stored until the destination mobile device **106**, **120** is available, and forwarded to the destination mobile device **106**,

120. The SMS entity may be, for example, a voicemail server that provides voicemail notifications via SMS, an advertising server, an Internet website, an e-mail server that provides e-mail notifications via SMS, a computer-based SMS client, and the like.

The MMSCs **112**, **116** provide a similar store and forward function for MMS messages in accordance with MMS standard protocols. The MMSCs **112**, **116** are a combination of hardware and software. For example, the MMSCs **112**, **116** are responsible for receiving MMS message content, storing the message content, dynamically generating an URL link for the message content, generating an MMS notification message including an URL pointer to the dynamically generated URL link, sending the MMS notification message to a designated recipient mobile device, and providing the MMS message content upon request from the recipient mobile device. In some embodiments, the MMSCs **112**, **116** are configured to communicate with a wireless application protocol (WAP) proxy server/gateway to provide the MMS message to the recipient device. In some embodiments, the MMSCs **112**, **116** are configured to communicate with the SMSCs **110**, **114** to perform various functions, such as sending an MMS notification message to the recipient mobile device via WAP push over SMS.

Wireless network B **104** also includes a RAN **118** that facilitates communication between a second mobile device **120** and the SMSC **114** and/or the MMSC **116**. The mobile device **120** may be any of the aforementioned device types, similar to the mobile device **106** as described above.

In some embodiments, a user of the first mobile device **106** and a user of the second mobile device **120** communicate using SMS, EMS, and/or MMS messaging services. In the illustrated embodiment, wireless network A **102** and wireless network B **104** are separate wireless networks. In some embodiments, wireless network A **102** and wireless network B **104** are operated by different service providers. In other embodiments, wireless network A **102** and wireless network B **104** are operated by the same service provider. In some embodiments, the mobile devices **106**, **120** operate in the same wireless network. The mobile devices **106**, **120** may exchange messages with other mobile devices (not illustrated) operating in the illustrated wireless communications network **100** or another wireless or landline network (not illustrated).

Referring now to FIG. 2, a schematic block diagram of an exemplary mobile device **200** is illustrated. Although connections are not shown between the components illustrated in FIG. 2, the components can interact with each other to carry out device functions. In some embodiments, for example, the components are arranged so as to communicate via one or more busses (not shown). It should be understood that FIG. 2 and the following description are intended to provide a general understanding of a suitable environment in which the various aspects of some embodiments of the present disclosure can be implemented.

In some embodiments, the mobile devices **106**, **120** illustrated in FIG. 1 are configured like the mobile device **200**, now described in detail. In some embodiments, the mobile device **200** is a multimode headset and has a variety of computer readable media, including, for example, volatile media, non-volatile media, removable media, and non-removable media. The term "computer-readable media" and variants thereof, as used in the specification and claims, refers to storage media and communication media. In some embodiments, storage media includes volatile and/or non-volatile, removable, and/or non-removable media. For example, storage media includes random access memory (RAM), read-

only memory (ROM), electrically erasable programmable read-only memory (EEPROM), solid state memory or other memory technology, CD ROM, DVD, or other optical disk storage, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium that can be used to store the desired information and that can be accessed by the mobile device **200**.

As illustrated in FIG. 2, the mobile device **200** includes a display **202** for displaying multimedia such as, for example, application graphical user interfaces (GUIs) (e.g., as illustrated in FIGS. 5, 6), text, images, video, telephony functions such as Caller ID data, setup functions, menus, music, meta-data, messages, wallpaper, graphics, Internet content, device status, preferences settings, map and location data, presence profile selection, and the like. The illustrated mobile device **200** also includes a processor **204** for processing data and/or executing computer-executable instructions of one or more applications, and a memory **206** for storing data and/or one or more applications **208**.

In some embodiments, the application(s) **208** include a user interface (UI) application **210**. The UI application **210** interfaces with a client **212** (e.g., an operating system (OS)) to facilitate user interaction with device functionality and data. In some embodiments, the client **212** is one of Symbian OS, Microsoft® Windows® Mobile OS (available from Microsoft® Corporation of Redmond, Wash.), Palm® webOS™ (available from Palm® Corporation of Sunnyvale, Calif.), Palm® OS (available from Palm® Corporation of Sunnyvale, Calif.), RIM® BlackBerry® OS (available from Research In Motion Limited of Waterloo, Ontario, Canada), Apple® iPhone® OS (available from Apple® Corporation of Cupertino, Calif.), or Google™ Android™ OS (available from Google™ of Mountain View, Calif.). These operating systems are merely exemplary of the operating systems that can be used in accordance with the embodiments disclosed herein. Other operating systems are contemplated.

The UI application **210** aids a user in entering message content, viewing received messages, answering/initiating calls, entering/deleting data, entering and setting user IDs and passwords, configuring settings, manipulating address book content and/or settings, interacting with other applications **214**, and the like. In some embodiments, the other applications **214** include, for example, message content filtering applications, messaging applications (e.g., SMS, EMS, MMS applications) presence applications, text-to-speech applications, speech-to-text applications, add-ons, plug-ins, email applications, music applications, video applications, camera applications, location service applications (LSAs), power conservation applications, game applications, productivity applications, entertainment applications, enterprise applications, combinations thereof, and the like. The applications **208** are stored in the memory **206** and/or in a firmware **216**, and are executed by the processor **204**. The firmware **216** may also store code for execution during device **200** power up, for example.

The illustrated mobile device **200** also includes an input/output (I/O) interface **218** for input/output of data, such as, for example, location information, filtering rule information, presence status information, selecting message content filtering options, user IDs, passwords, and application initiation (start-up) requests. In some embodiments, the I/O interface **218** is a hardware connection, such as, for example, a USB, mini-USB, audio jack, PS2, IEEE 1394, serial, parallel, Ethernet (RJ48) port, RJ11 port, or the like. In some embodiments, the I/O interface **218** accepts other I/O devices such as, for example, keyboards, keypads, mice, interface tethers, stylus pens, printers, thumb drives, touch screens, multi-touch

screens, touch pads, trackballs, joysticks, microphones, remote control devices, monitors, displays, liquid crystal displays (LCDs), combinations thereof, and the like. It should be appreciated that the I/O interface **218** may be used for communications between the mobile device **200** and a network or local device, instead of, or in addition to, a communications component **220**.

The communications component **220** interfaces with the processor **204** to facilitate wired/wireless communications with external systems. Example external systems include, but are not limited to, intranets, network databases, network storage systems, cellular networks, location servers, presence servers, Voice over Internet Protocol (VoIP) networks, local area networks (LANs), wide area networks (WANs), metropolitan area networks (MANs), personal area networks (PANs), and other networks. In some embodiments, the external systems are implemented using WIFI, WIMAX, combinations and/or improvements thereof, and the like. In some embodiments, the communications component **220** includes a multimode communications subsystem for providing cellular communications via different cellular technologies. In some embodiments, for example, a first cellular transceiver **222** operates in one mode, such as, Global System for Mobile communications (GSM), and an Nth cellular transceiver **224** operates in a different mode, such as Universal Mobile Telecommunications System (UMTS). While only two cellular transceivers **222**, **224** are illustrated, it should be appreciated that a plurality of transceivers can be included.

The illustrated communications component **220** also includes an alternative communications transceiver **226** for use by other communications technologies such as, for example, WIFI, WIMAX, BLUETOOTH, infrared, infrared data association (IRDA), near field communications (NFC), RF, and the like. In some embodiments, the communications component **220** also facilitates reception from terrestrial radio networks, digital satellite radio networks, Internet-based radio services networks, combinations thereof, and the like. The communications component **220** can process data from a network such as, for example, the Internet, an intranet (e.g., business intranet), a home broadband network, a WIFI hotspot, and the like, via an ISP, DSL provider, or broadband provider. In some embodiments, the communications component **220** facilitates the transmission of authentication information from the mobile device **200** to a network for processing in accordance with the methods described herein.

Audio capabilities for the mobile device **200** can be provided by an audio I/O component **228** that includes a speaker for the output of audio signals and a microphone to collect audio signals.

The illustrated mobile device **200** also includes a slot interface **230** for accommodating a subscriber identity system **232** such as, for example, a subscriber identity module (SIM) card or universal SIM (USIM) card. Alternatively, the subscriber identity system **232** may be manufactured into the device **200**, thereby obviating the need for a slot interface **230**. In some embodiments, the subscriber identity system **232** is programmed by a manufacturer, a retailer, a user, a computer, a network operator, or the like.

The illustrated mobile device **200** also includes an image capture and processing system **234** (image system). Photos may be obtained via an associated image capture subsystem of the image system **234**, for example, a camera. The illustrated mobile device **200** also includes a video system **236** for capturing, processing, recording, modifying, and/or transmitting video content. Photos and videos obtained using the image system **234** and the video system **236**, respectively,

may be added as message content to an MMS message and sent to another mobile device.

The illustrated mobile device **200** also includes a location component **238** for sending and/or receiving signals such as, for example, GPS data, assisted GPS (A-GPS) data, WIFI/WIMAX and/or cellular network triangulation data, combinations thereof, and the like, for determining a location of the mobile device **200**. In some embodiments, the location component **238** interfaces with cellular network nodes, telephone lines, satellites, location transmitters and/or beacons, wireless network transmitters and receivers, for example, WIFI hotspots, radio transmitters, combinations thereof, and the like. In some embodiments, the mobile device **200** is configured to determine whether message content received in a message is appropriate for a given location of the mobile device **200** determined using the location component **238**, as will be described in further detail below with reference to FIG. 3.

Using the location component **238**, the mobile device **200** obtains, generates, and/or receives data to identify its location, or transmits data used by other devices to determine the location of the mobile device **200**. In some embodiments, the location of the mobile device **200** is used by a message content filtering application to determine whether message content of a received message is appropriate or inappropriate for the location of the mobile device **200**. The message content filtering application also determines whether inappropriate content should be treated as appropriate after the mobile device **200** travels to a new, safe location. An exemplary method for selectively filtering message content received at the mobile device **200** based upon a current location of the mobile device **200** is described below with reference to FIG. 3. An exemplary GUI of a message content filtering application is illustrated in FIGS. 5 and 6.

The illustrated mobile device **200** also includes a power source **240**, such as batteries and/or other power subsystem (AC or DC). The power source **240** can interface with an external power system or charging equipment via a power I/O component **242**.

Referring now to FIG. 3, a method **300** for selectively filtering message content received at the mobile device **200** based upon a current location of the mobile device is illustrated, according to an embodiment of the present disclosure. It should be understood that the steps of the method **300** are not necessarily presented in any particular order and that performance of some or all the steps in an alternative order is possible and is contemplated. The steps have been presented in the demonstrated order for ease of description and illustration. Steps can be added, omitted and/or performed simultaneously without departing from the scope of the appended claims. It should also be understood that the illustrated method **300** can be ended at any time. In certain embodiments, some or all steps of this process, and/or substantially equivalent steps can be performed by execution of computer-readable instructions stored or included on a computer readable medium, such as the memory **206** of the mobile device **200**. In some embodiments, the other applications **214** of the mobile device **200** include a message content filtering (MCF) application configured to perform the steps of the method **300**.

The method **300** begins and flow proceeds to block **302**, whereat the MCF application detects a message being received. The message may be an SMS message, an EMS message, or an MMS message, as described above. The message includes message content, such as text, graphics, audio, and/or video. At block **304**, the MCF application determines the current location of the mobile device **200**. The mobile

device **200** may use the location component **238** to determine its location. A message content filtering application may be configured to communicate with a LSA to obtain the current location of the mobile device.

At block **306**, the MCF application analyzes the message content to determine whether any portion of the message content is considered inappropriate by the user of the mobile device **200** based upon a filtering rule established for the current location. The filtering rule may include a location definition defining whether a given location is considered safe or banned and at least one filtering condition for the given location.

The location definition may be a precise location defined by a physical address or latitude/longitude coordinates, for example. Alternatively, the location definition may define an area of any shape and size. In some embodiments, the location definition includes a location center and an area including a specified distance around the location center. The location definition may be user definable or may be dynamically generated based upon movement patterns of the mobile device **200** with or without additional input from a user.

In some embodiments, a banned location is defined but a safe location is not defined. In this case, when the mobile device **200** leaves a banned location, the mobile device **200** enters what is considered by the MCF application to be a default safe location and modifies a message based upon a default filtering rule, such as allowing all or some content at the default safe location.

The MCF application may provide several ways for a user to create a new safe or banned location. For example, the MCF application may provide an option to create a new location using a map tool, using a current location of the mobile device **200**, or by manually entering location information. These and other options are described in further detail with reference to FIG. 5.

The filtering rule includes at least one filtering condition for a given safe or banned location. Filtering conditions include, but are not limited to, allow/ban content based upon a specified list of content (e.g., words, phrases, characters, letters, numbers, symbols, graphic file names, explicit graphic types, video file names, explicit video types, spoken words, music types, ringtone types, and explicit audio types) allow/ban all content, allow/ban content from a contact, allow/ban pre-rated content based upon the rating, allow/ban based upon parental control settings, and the like.

At decision block **308**, a determination is made as to whether any portion of the message content should be considered inappropriate based upon the filtering rule established for the current location. If it is determined that any portion of the message content should be considered inappropriate, flow is to block **310**. At block **310**, the MCF application modifies the inappropriate portion of the message content such that the inappropriate portion is indiscernible to the user when the mobile device **200** is in the current location.

In some embodiments, the MCF application modifies the inappropriate portion of the message content by blocking the inappropriate portion of the message content. Blocking text, video, and/or graphics content may include blacking out, graying out, whiting out, or otherwise covering the inappropriate portion of the message content such that it is not viewable.

In some embodiments, the MCF application modifies the inappropriate portion of the message content by temporarily removing the inappropriate portion of the message content. When the mobile device **200** arrives at a safe location, the temporary removal of the inappropriate portion is lifted. The previously considered inappropriate portion is then consid-

11

ered appropriate by the MCF application and available to be presented to the user on the mobile device **200**.

In some embodiments, the MCF application modifies the inappropriate portion of the message content by altering the inappropriate portion of the message content. Altering audio content may include introducing noise into the audio signal, introducing other audio into the audio signal, distorting the audio, speeding up or slowing down playback of the audio, changing the frequency of the audio, or otherwise altering the audio such that the audio is not discernable. Altering video content may include introducing frames to the video, introducing artifacts, introducing clipping, introducing aliasing, distorting the video, blurring the video, increasing or decreasing the frame rate, introducing other video, or otherwise altering the video such that the video is not discernable. Altering text content may include adding characters, symbols, numbers, and/or letters to the text content, changing the text content to other characters, symbols, numbers, and/or letters, removing a portion of the text so that the remaining portion is not discernable, skewing the text, blurring the text, introducing artifacts, increasing/decreasing the size of the text, distorting the text, changing the orientation of the text, or otherwise altering the text. Altering graphics may include, but is not limited to, filtering the graphics with at least one filter, introducing artifacts, introducing aliasing, blurring the graphics, stretching the graphics, increasing/decreasing the size of the graphics, changing the orientation of the graphics, distorting the graphics, or otherwise altering the graphics.

Returning to FIG. 3, at block **312**, the MFC application presents only the appropriate portion of the message content to the user. The MFC application generally presents the appropriate portion in a manner consistent with the type of message content included in the appropriate portion. For example, text will be presented as text on a display, such as the display **202** of the mobile device **200**, as will graphics and video, and audio will be presented using a speaker of the mobile device **200**, headphones or external speakers (e.g., vehicle, stationary, or portable speakers) connected to a headphone jack of the mobile device, or via another audio output device, such as the audio I/O **228**. It is also contemplated that text content may be converted to audio content via a text-to-speech application (e.g., one of the other applications **214**) stored in the memory **206** of the mobile device, and that audio content may be converted to text content via a speech-to-text application (e.g., one of the other applications **214**).

At block **314**, the MFC application monitors the movement of the mobile device **200**, for example, using the location component **238** of the mobile device **200**. In some embodiments, the MFC application requests location information periodically from the location component **238** or a location services application of the other applications **214**. When the mobile device **200** enters a location defined as a safe location, at block **316**, the MFC application modifies the message content based upon a filtering rule established for the safe location. The message content previously considered to be inappropriate at the original location (current location above) may now be considered appropriate and is modified accordingly. For example, content modified to be indiscernible to the user or others is returned to its original condition. At block **318**, the MFC application presents the message content to the user. The method **300** can end.

If, at block **308**, it is determined that no portion of the message is considered inappropriate, flow is to block **318**. At block **318**, the MFC application presents the message content to the user. The method **300** can end.

Referring now to FIG. 4, a method **400** for selectively filtering message content received at the mobile device **200**

12

based upon a presence status of the mobile device is illustrated, according to an embodiment of the present disclosure. It should be understood that the steps of the method **400** are not necessarily presented in any particular order and that performance of some or all the steps in an alternative order is possible and is contemplated. The steps have been presented in the demonstrated order for ease of description and illustration. Steps can be added, omitted and/or performed simultaneously without departing from the scope of the appended claims. It should also be understood that the illustrated method **400** can be ended at any time. In certain embodiments, some or all steps of this process, and/or substantially equivalent steps can be performed by execution of computer-readable instructions stored or included on a computer readable medium, such as the memory **206** of the mobile device **200**. In some embodiments, the applications **208** of the mobile device **200** include an MCF application configured to perform the steps of the method **400**.

The term presence as used herein refers to, for example, the availability, activity level, or operating state of a user on a network. The ability for users to monitor each other's presence is a feature offered in connection with some messaging applications of the present disclosure (e.g., other applications **214**). For example, some messaging applications have a buddy list or contact list feature that displays a contact list and a presence status for each contact in the list. The presence status indicates a user's availability and/or current activity so that others can determine whether to send a message to a particular contact. In context of the present method **400**, a user's presence status, for example, available, not available, do not disturb, or custom status, is used by the MFC application to determine whether message content received in an SMS, EMS, or MMS message should be considered appropriate or inappropriate.

The method **400** begins and flow proceeds to block **402**, whereat the MCF application detects a message being received. The message may be an SMS message, an EMS message, or an MMS message, as described above. The message includes message content, such as text, graphics, audio, and/or video. At block **404**, the MCF application analyzes the message content to determine whether any portion of the message content would be considered inappropriate by the user of the mobile device **200** based upon a filtering rule established for the current presence status of the user. The filtering rule includes at least one filtering condition for a given presence status. Filtering conditions include, but are not limited to, allow/ban content based upon a specified list, allow/ban all content, allow/ban content from a contact, allow/ban pre-rated content based upon the rating, allow/ban based upon parental control settings, and the like.

At decision block **406**, a determination is made as to whether any portion of the message content should be considered inappropriate based upon the filtering rule established for the current presence status. If it is determined that any portion of the message content should be considered inappropriate, flow is to block **408**. At block **408**, the MCF application modifies the inappropriate portion of the message content such that the inappropriate portion is indiscernible to the user when the mobile device **200** is in the current location.

In some embodiments, the MCF application modifies the inappropriate portion of the message content by blocking the inappropriate portion of the message content. Blocking text, video, and/or graphics content may include blacking out, graying out, whiting out, or otherwise covering the inappropriate portion of the message content such that it is not viewable. In some embodiments, the MCF application modifies the inappropriate portion of the message content by tempo-

13

rarily removing the inappropriate portion of the message content. In some embodiments, the MCF application modifies the inappropriate portion of the message content by altering the inappropriate portion of the message content. Altering audio content may include introducing noise into the audio signal, introducing other audio into the audio signal, distorting the audio, speeding up or slowing down playback of the audio, changing the frequency of the audio, or otherwise altering the audio such that the audio is not discernable. Altering video content may include introducing frames to the video, introducing artifacts, introducing clipping, introducing aliasing, distorting the video, blurring the video, increasing or decreasing the frame rate, introducing other video, or otherwise altering the video such that the video is not discernable. Altering text content may include adding characters, symbols, numbers, and/or letters to the text content, changing the text content to other characters, symbols, numbers, and/or letters, removing a portion of the text so that the remaining portion is not discernable, skewing the text, blurring the text, introducing artifacts, increasing/decreasing the size of the text, distorting the text, changing the orientation of the text, or otherwise altering the text. Altering graphics may include, but is not limited to, filtering the graphics, introducing artifacts, introducing aliasing, blurring the graphics, stretching the graphics, increasing/decreasing the size of the graphics, changing the orientation of the graphics, distorting the graphics, or otherwise altering the graphics.

Returning to FIG. 4, at block 410, the MFC application presents only the appropriate portion of the message content to the user. The MFC application generally presents the appropriate portion in a manner consistent with the type of message content included in the appropriate portion. For example, text will be presented as text on a display, such as the display 202 of the mobile device 200, as will graphics and video, and audio will be presented using a speaker of the mobile device 200, headphones or external speakers (e.g., vehicle, stationary, or portable speakers) connected to a headphone jack of the mobile device, or via another audio output device, such as the audio I/O 228. It is also contemplated that text content may be converted to audio content via a text-to-speech application (e.g., one of the other applications 214) stored in the memory 206 of the mobile device, and that audio content may be converted to text content via a speech-to-text application (e.g., one of the other applications 214).

At block 412, the MFC application detects a change from the current presence status to a new presence status. At block 414, the MFC application modifies the message content based upon a filtering rule established for the new presence status. The message content previously considered to be inappropriate under the previous presence status is now considered appropriate and is modified accordingly. For example, content modified to be indiscernible to the user or others is returned to its original condition. At block 416, the MFC application presents the message content to the user. The method 400 can end.

If, at block 406, it is determined that no portion of the message should be considered inappropriate, flow is to block 416. At block 416, the MFC application presents the message content to the user. The method 400 can end.

In some alternative embodiments, the methods 300, 400 may be performed based solely upon a time-based filtering rule or based upon a time-based filtering rule in addition to a location-based or presence-based filtering rule. Under certain time-based filtering rules, for example, message content is not filtered at all during certain time periods (e.g., weekends, after 6 PM, a particular date) even though the mobile device

14

200 is within a banned location or when the user's presence status is set such that certain message content should be banned.

Referring now to FIG. 5, an exemplary Graphical User Interface (GUI) 500 of an MCF application operating on the exemplary mobile device 200 of FIG. 2 is illustrated, according to one embodiment of the present disclosure. It should be understood that the layout, font type, font style, color, filtering options, menu design, and exemplary selection choices are provided merely as one embodiment in which a GUI of the MCF application may be configured and are not intended to reduce the scope of the appended claims.

The illustrated GUI 500 shows that an option has been selected to enable location-based message content filtering for text and multimedia content. Other options are available to enable presence-based message content filtering as an alternative to or in addition to the location-based filtering option, as described below with respect to FIG. 6.

The illustrated GUI 500 also includes options to create a new location definition for a safe or banned location. A safe location, for example, may be created or defined using a map tool, the current location of the mobile device 200, or manual entry. If the map tool option is selected, the user may be presented with a map on which the user defines boundaries of the safe location. In some embodiments, a user defines the safe location by drawing the boundaries of the safe location on a digital map. In some embodiments, a user defines a center point (e.g., manually entered or retrieved via the location component 238 of the mobile device 200) and a radius to define the safe location. If the current location option is selected, as illustrated, the MFC application will define the safe location for the current location. The MFC application may add a default distance (e.g., 50 feet, 100 feet, 2 miles, etc.) around the specified or determined location to be included in the safe location definition. Alternatively, the user may specify a distance around the current location to be included in the safe location definition.

If the manual entry option for location creation is selected, the user may enter at least one of country name, state name, province name, zip code, county name, city name, physical address, neighborhood, latitude/longitude coordinates, point-of-interest, or other information to define the safe location. The illustrated GUI 500 includes similar options to create a new banned location.

The illustrated GUI 500 also includes filtering rule settings. As illustrated, a user may select a saved safe location or a saved banned location and apply at least one filtering condition for that location. An option for adding new filtering conditions is also illustrated. In the illustrated example, a user has selected School and has applied a Ban—List B filtering condition, indicating that when the user's mobile device is located within a location defined for the banned location School, any message content that is included in list B is modified so as to be indiscernible to the user and other potential viewers/listeners until the mobile device 200 reaches a safe location.

Referring now to FIG. 6, an exemplary Graphical User Interface (GUI) 600 of an MCF application operating on the exemplary mobile device 200 of FIG. 2 is illustrated, according to one embodiment of the present disclosure. It should be understood that the layout, font type, font style, color, filtering options, menu design, and exemplary selection choices are provided merely as one embodiment in which a GUI of the MCF application may be configured and are not intended to reduce the scope of the appended claims.

The illustrated GUI 600 shows that an option has been selected to enable presence-based message content filtering

15

for text content. Other options are available to enable location-based message content filtering as an alternative to or in addition to the presence-based filtering option, as described above.

The illustrated GUI **600** also includes options to use a default presence profile, set a custom presence profile, or create a new presence profile. A presence profile includes presence statuses and filtering conditions for each presence status. For example, a presence status of not available may include a filtering condition to ban all content and a presence status of not available may include a filtering condition to allow all content. In some embodiments, a user's presence status is updated manually by the user. In alternative embodiments, a user's presence status is updated automatically based upon a predefined condition, such as a location, a time, a particular application being used on the mobile device **200**, a minute or data usage condition, (e.g., presence status is not available if minute and/or data usage for a billing period has exceeded a specified amount), a battery life condition (e.g., presence status is not available if battery level is near, at, or below a specified minimum).

The illustrated GUI **600** also includes filtering rule settings. As illustrated, a user may select a presence status for the active presence profile and apply at least one filtering condition for that presence status. This process may be repeated for each presence status defined for the active presence profile. An option for adding new filtering conditions is also illustrated. In the illustrated example, a user has selected Not Available as the presence status and has applied a Ban—List A filtering condition, indicating that when the user's active profile is Custom Presence Profile **2** and the user's presence status is set to Not Available, any message content that is included in list A is modified so as to be indiscernible to the user and other potential viewers/listeners until the user's presence status changes to a new presence status which does not include a similar filtering condition.

The aforementioned embodiments often describe message content filtering performed at a mobile device (e.g., the mobile device **200**). Alternative embodiments are contemplated in which message content filtering is performed at a network element, such as, for example, an SMSC, an MMSC, or a dedicated filtering server configured to filter message content.

In one such embodiment, a message content filtering (MCF) application is stored in a memory of the network element and is configured to perform filtering functions consistent with the functions performed by the MCF application as described above with reference to FIGS. **3** and **4**. For example, while FIG. **3** is described with reference to an MCF application stored on the mobile device **200**, in some embodiments, the network element uses a similar MCF application to perform like functions at the network level. It is contemplated that the steps of the method **300** illustrated in FIG. **3** may be performed by the network element as opposed to the mobile device **200**. Some steps, however, may require slight modification.

For example, the step illustrated in block **302** may be replaced with a step for receiving a message directed to the mobile device **200**. After the message is received, the network element determines a current location of the mobile device using the MCF application stored in the network element to communicate with a location server to obtain location information for the mobile device **200** so as to be consistent with block **304**. The step illustrated in block **312** for presenting only the appropriate portion of the message content to the user may be replaced with a step sending the appropriate portion of the message content in a first message to the mobile device

16

200. Similarly, the step illustrated in block **318** for presenting the message content to the user may be replaced with a step for sending the message content in a second message to the mobile device **200**. The message content in the second message may include the entire original message or only the new content not previously sent in the first message. In the latter example, the mobile device **200** is configured to combine the message content of the first message and the new message content of the second message.

In another embodiment, the SMSC, or the MMSC, where appropriate, receives a message and sends the message to a dedicated filtering server. The dedicated filtering server determines, based upon a filtering rule, whether the message includes inappropriate message content. If the message includes inappropriate message content, the dedicated filtering server modifies the message content as described above.

In another embodiment, the network element receives a message and modifies the message to include an indication that the message must be modified after it is received at the mobile device **200**. If the short message peer-to-peer (SMPP) protocol is used, for example, the user data header (UDH) may be modified to include the indication that the message should be modified based upon a particular filtering rule known to the mobile device **200**. In this example, the mobile device **200** receives the message, checks the UDH, and modifies the message based upon the filtering rule identified in the UDH. Alternatively, the network element adds message modification instructions to the message header or message body. In this alternative, the mobile device **200** modifies the message according to the instructions, removes the instructions, and presents the modified message to the user.

The above embodiments are equally applicable to message content being filtered based upon filtering rules established for a user's presence status. In this case, the network element communicates with a presence server to obtain current and subsequent presence statuses for a user and proceeds according to the method **400** of FIG. **4**. Some steps of the method **400**, however, may require slight modifications similar to those described above with reference to a modified method **300**.

The law does not require and it is economically prohibitive to illustrate and teach every possible embodiment of the present claims. Hence, the above-described embodiments are merely exemplary illustrations of implementations set forth for a clear understanding of the principles of the disclosure. Variations, modifications, and combinations may be made to the above-described embodiments without departing from the scope of the claims. All such variations, modifications, and combinations are included herein by the scope of this disclosure and the following claims.

What is claimed is:

1. A computer-readable storage medium having stored thereon computer-executable instructions that, when executed by a processor, cause the processor to perform operations, for selectively filtering message content received at a mobile device, based upon a current location of the mobile device, comprising:

detecting a message transmitted for receipt at the mobile device, the message comprising message content;
determining the current location of the mobile device;
analyzing the message content to determine, based upon a filtering rule established for the mobile device corresponding to the current location, whether any portion of the message content is inappropriate;

17

if it is determined that no portion of the message content is inappropriate, presenting the message content to a user of the mobile device when the mobile device is at the current location; and

if it is determined that any portion of the message content is inappropriate based upon the filtering rule established for the mobile device corresponding to the current location:

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the mobile device is at the current location;

presenting any appropriate portion of the message content to the user of the mobile device;

monitoring movement of the mobile device from the current location to a safe location, wherein a filtering rule established for the mobile device for the safe location considers the inappropriate portion of the message content to be appropriate when the mobile device is at the safe location;

modifying the message content based upon the filtering rule established for the mobile device for the safe location, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user when the mobile device is at the safe location; and

presenting the message content to the user of the mobile device when the mobile device is at the safe location.

2. The computer-readable storage medium of claim 1, wherein detecting the message comprises detecting a text message, the message content including text.

3. The computer-readable storage medium of claim 1, wherein detecting the message comprises detecting a multimedia message, the message content including at least two of text, graphics, audio, and video.

4. The computer-readable storage medium of claim 1, wherein analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location comprises analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location and an area around the current location.

5. The computer-readable storage medium of claim 1, wherein analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location comprises analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location, the filtering rule being defined by the user of the mobile device.

6. The computer-readable storage medium of claim 5, wherein the filtering rule being defined by the user of the mobile device comprises the filtering rule being defined based upon a content rating assigned to message content.

7. The computer-readable storage medium of claim 1, wherein analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location, comprises analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current location, the filtering rule being set by a wireless service provider.

8. The computer-readable storage medium of claim 1, wherein:

18

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the mobile device is at the current location comprises blocking the inappropriate portion of the message content; and

modifying the message content based upon the filtering rule established for the mobile device for the safe location, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user when the mobile device is at the safe location, comprises unblocking the previously considered inappropriate portion of the message content.

9. The computer-readable storage medium of claim 1, wherein

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the mobile device is at the current location, comprises temporarily removing the inappropriate portion of the message content; and

modifying the message content based upon the filtering rule established for the mobile device for the safe location, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user when the mobile device is at the safe location, comprises adding the previously considered inappropriate portion of the message content back into the message content.

10. The computer-readable storage medium of claim 1, wherein:

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the mobile device is at the current location, comprises altering the inappropriate portion of the message content; and

modifying the message content based upon the filtering rule established for the mobile device for the safe location, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user when the mobile device is at the safe location, comprises undoing the altering of the previously considered inappropriate portion of the message content.

11. A computer-readable storage medium, for selectively filtering message content received at a mobile device, based upon a current presence status of a user of the mobile device, comprising:

detecting a message transmitted for receipt at the mobile device, the message comprising message content;

analyzing the message content to determine, based upon a filtering rule established for a current presence status of a user of the mobile device, whether any portion of the message content is inappropriate;

if it is determined that no portion of the message content is inappropriate, presenting the message content to the user of the mobile device; and

if it is determined that any portion of the message content is inappropriate based upon the filtering rule established for the current present status of the user of the mobile device:

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the current presence status is active;

presenting the appropriate portion of the message content to the user of the mobile device;

detecting a change from the current presence status to a new presence status, the new presence status trigger-

19

ing a new filtering rule to be implemented that considers the inappropriate portion of the message content previously determined to be inappropriate as being appropriate for the new presence status;

modifying the message content based upon the new filtering rule, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user; and
presenting the message content to the user of the mobile device when the new presence status is active.

12. The computer-readable storage medium of claim 11, wherein analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current presence status comprises analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current presence status, the filtering rule being set by the user of the mobile device.

13. The computer-readable storage medium of claim 12, wherein the filtering rule being defined based upon criteria set by the user of the mobile device, in setting the filtering rule, comprises the filtering rule being defined based upon a content rating assigned to message content.

14. The computer-readable storage medium of claim 11, wherein analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current presence status comprises analyzing the message content to determine whether any portion of the message content is inappropriate based upon the filtering rule established for the current presence status, the filtering rule being set by a wireless service provider.

15. The computer-readable storage medium of claim 11, wherein:

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the current presence status is active comprises blocking the inappropriate portion of the message content; and

modifying the message content based upon the new filtering rule, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user comprises unblocking the previously considered inappropriate portion of the message content.

16. The computer-readable storage medium of claim 11, wherein

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user during the current presence status comprises temporarily removing the inappropriate portion of the message content; and

modifying the message content based upon the new filtering rule, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user comprises adding the previously considered inappropriate portion of the message content back into the message content.

17. The computer-readable storage medium of claim 11, wherein:

20

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the current presence status is active comprises altering the inappropriate portion of the message content; and

modifying the message content based upon the new filtering rule, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user comprises undoing the altering of the previously considered inappropriate portion of the message content.

18. The computer-readable storage medium of claim 11, wherein detecting the message comprises detecting a text message, the message content including text.

19. The computer-readable storage medium of claim 11, wherein detecting the message comprises detecting a multimedia message, the message content including at least two of text, graphics, audio, and video.

20. A mobile device, configured to selectively filter message content in connection with the mobile device, comprising:

a transceiver for receiving message content;

a processor operably connected to the transceiver; and

a memory, operably connected to the processor, the memory having instructions which, when executed by the processor, cause the processor to perform operations comprising:

detecting a message transmitted for receipt at the mobile device, the message comprising message content;

analyzing the message content to determine, based upon a filtering rule established for a current presence status of a user of the mobile device, whether any portion of the message content is inappropriate;

if it is determined that no portion of the message content is inappropriate, presenting the message content to the user of the mobile device; and

if it is determined that any portion of the message content is inappropriate based upon the filtering rule established for the current present status of the user of the mobile device;

modifying the inappropriate portion of the message content, such that the inappropriate portion is indiscernible to the user when the current presence status is active;

presenting the appropriate portion of the message content to the user of the mobile device;

detecting a change from the current presence status to a new presence status, the new presence status triggering a new filtering rule to be implemented that considers the inappropriate portion of the message content previously determined to be inappropriate as being appropriate for the new presence status;

modifying the message content based upon the new filtering rule, such that the inappropriate portion of the message content previously determined to be inappropriate is available to the user; and

presenting the message content to the user of the mobile device when the new presence status is active.
